Overview

Assume that the received pressure field $p(\mathbf{x}_r, t; \mathbf{x}_s)$ generated by a causal isotropic point radiator at source position $\mathbf{x} = \mathbf{x}_s$ satisfies the constant density acoustic wave equation,

$$\frac{1}{v^2} \frac{\partial^2 p}{\partial t^2} - \Delta p = \delta(\mathbf{x} - \mathbf{x}_s) f(t) \quad \text{in } \mathbb{R}^2. \quad (1)$$

$$p|_{t=0} = \frac{\partial p}{\partial t} \Big|_{t=0} = 0 \quad (2)$$

Let's introduce the forward modeling operator $S[v]$ to relate the velocity $v(x, z)$ and wavelet function $f(t)$ to the scattering field at the receiver \mathbf{x}_r ,

$$S[v, f](\mathbf{x}_r, t; \mathbf{x}_s) = p(\mathbf{x}_r, t; \mathbf{x}_s). \quad (3)$$

Full Waveform Inversion

Given recorded traces $d(\mathbf{x}_r, t; \mathbf{x}_s)$, find velocity v and wavelet function f such that $S[v, f] = d$.

- FWI via data fitting,

$$J_{\text{FWI}}[v, f] = \frac{1}{2} \sum_{\mathbf{x}_r, \mathbf{x}_s} \int |S[v, f](\mathbf{x}_r, t; \mathbf{x}_s) - d(\mathbf{x}_r, t; \mathbf{x}_s)|^2 dt. \quad (4)$$

- FWI objective function is quadratic with respect to f , but highly nonlinear and nonconvex in velocity v (frequency dependent).
- Cycle skipping problem (eg. Symes, 1994).

Extended Modeling & Null Space

Extended Modeling:

Let $\bar{f}(\mathbf{x}_r, \mathbf{x}_s, t)$ be the extended model of $f(t)$, define the extended modeling operator

$$\bar{S}[v, \bar{f}] = \bar{p}(\mathbf{x}_r, t; \mathbf{x}_s)$$

where \bar{p} is the solution of (1)-(2) with source function being \bar{f} .

Null Space (Annihilator):

- Differential semblance operator $A = \partial_{z_s}$ (see Symes (1994));
- t -moment operator after source signature deconvolution $A = tf^{-1}(t)$ (eg. deconvolution-based by Luo and Sava (2011), AWI by Warner (2014)).

MSWI

Matched Source Waveform Inversion (MSWI) is stated as follows,

$$J_{\text{MS}}[v] = \frac{1}{2} \sum_{\mathbf{x}_r, \mathbf{x}_s} \int |A\bar{f}|^2 dt \quad (5)$$

$$s.t. \bar{S}[v, \bar{f}](\mathbf{x}_r, t; \mathbf{x}_s) = d(\mathbf{x}_r, t; \mathbf{x}_s). \quad (6)$$

Key feature: Even given wrong velocity, data fitting is perfect, hence no cycle skipping problem!

Factorization of Tangent Operator

Under single arrival approximation, we have

$$\bar{S}[v, \bar{f}](\mathbf{x}_r, t; \mathbf{x}_s) \approx a(\mathbf{x}_r, \mathbf{x}_s) \bar{f}(\mathbf{x}_r, \mathbf{x}_s, t - \tau(\mathbf{x}_r, \mathbf{x}_s))$$

Then taking the first order variation of $\bar{S}[v, \bar{f}]$ formally gives us the desired factorization of operator

$$\begin{aligned} (D\bar{S}[v]\delta v)\bar{f}(\mathbf{x}_r, t; \mathbf{x}_s) &\approx a(\mathbf{x}_r, \mathbf{x}_s) \frac{\partial}{\partial t} \bar{f}(\mathbf{x}_r, \mathbf{x}_s, t - \tau(\mathbf{x}_r, \mathbf{x}_s)) (-D\tau[v]\delta v) \\ &\triangleq \bar{S}[v, Q[v, \delta v]\bar{f}]. \end{aligned}$$

where $D\tau[v]$ is the tangent operator of traveltime function, and $Q[v, \delta v]\bar{f}$ is bilinear operator with respect to δv and \bar{f} with

$$Q[v, \delta v] = -(D\tau[v]\delta v) \frac{\partial}{\partial t}.$$

Backprojection of Traveltime Differences

Taking the first order perturbation of J_{MS} , we have

$$DJ_{\text{MS}}[v]\delta v \approx \sum_{\mathbf{x}_r, \mathbf{x}_s} \int A^T A \bar{f} (D\tau[v] \delta v \bar{f}_t) dt$$

Hence the gradient is given by,

$$g \approx \sum_{\mathbf{x}_r, \mathbf{x}_s} D\tau[v]^T \left(\int (A^T A \bar{f}) \bar{f}_t dt \right)$$

Here $D\tau[v]^T$ is the adjoint operator of $D\tau[v]$, which backprojects its arguments along rays.

Adjoint Source in the Gradient

Assume that data is noise-free and well approximated by geometric optics,

$$d(\mathbf{x}_r, t; \mathbf{x}_s) \approx a^*(\mathbf{x}_r, \mathbf{x}_s) f^*(t - \tau[v^*](\mathbf{x}_r, \mathbf{x}_s)). \quad (7)$$

Denote by $\Delta\tau(\mathbf{x}_r, \mathbf{x}_s) = \tau[v^*](\mathbf{x}_r, \mathbf{x}_s) - \tau[v](\mathbf{x}_r, \mathbf{x}_s)$, then

- For differential semblance operator $A = \partial_{z_s}$,

$$\int (A^T A \bar{f}) \bar{f}_t dt \approx -\left(\frac{a^*}{a}\right)^2 \int \left(\frac{\partial f^*}{\partial t}\right)^2 dt \left(\frac{\partial}{\partial z_s}\right)^T \left(\frac{\partial}{\partial z_s} \Delta\tau[v](z_r, z_s)\right).$$

- For t -moment operator, we have

$$\int (A^T A \bar{f}) \bar{f}_t dt \approx -(a^*/a)^2 \Delta\tau[v](z_r, z_s).$$

Traveltime Tomography

Travel tomography attempts to minimize the difference between the computed traveltime and picked traveltime from data,

$$J_{\text{TT}} = \frac{1}{2} \sum_{\mathbf{x}_r, \mathbf{x}_s} \|\tau[v](\mathbf{x}_r, \mathbf{x}_s) - \tau[v^*](\mathbf{x}_r, \mathbf{x}_s)\|^2,$$

The gradient of J_{TT} is given by,

$$\nabla J_{\text{TT}} = - \sum_{\mathbf{x}_r, \mathbf{x}_s} D\tau[v]^T (\Delta\tau[v](z_r, z_s)).$$

 - Analysis of Gradient
 - Local Convexity of Hessian**
 - Relation with DSO formulation
- 4 Numerical Examples
- 5 Conclusion and Discussion

Local Convexity of Hessian

The Hessian of J_{MS} at consistent data $A\bar{f} = 0$ is given by

$$D^2 J[v^*](\delta v, \delta v) \approx \sum_{\mathbf{x}_r, \mathbf{x}_s} \int |[A, Q](v^*, \delta v)\bar{f}|^2 dt$$

where $[A, Q] = AQ - QA$.

- for $A = \partial_{z_s}$,

$$D^2 J[v^*](\delta v, \delta v) \approx \int \left(\frac{\partial f^*}{\partial t} \right)^2 dt \left(\sum_{\mathbf{x}_r, \mathbf{x}_s} \left| \frac{\partial}{\partial z_s} D\tau[v^*]\delta v \right|^2 \right)$$

- for $A = tf^{-1}(t)$,

$$D^2 J[v^*](\delta v, \delta v) \approx \sum_{\mathbf{x}_r, \mathbf{x}_s} |D\tau[v^*]\delta v|^2$$

Hessian of J_{MS} is proportional to the Hessian of a traveltime objective function, and is as convex as tomographic objective.

- 3 Analysis of Gradient and Hessian**
 - Analysis of Gradient
 - Local Convexity of Hessian
 - Relation with DSO formulation**
- 4 Numerical Examples
- 5 Conclusion and Discussion

Relation with DSO formulation

DSO formulation seeks the balance between data fitting and annihilator term, i.e.

$$J_{\alpha}[v, \bar{f}] = \frac{1}{2} \sum_{\mathbf{x}_r, \mathbf{x}_s} \int |\bar{S}[v, \bar{f}] - d|^2 dt + \frac{\alpha}{2} \sum_{\mathbf{x}_r, \mathbf{x}_s} \int |A\bar{f}|^2 dt.$$

- As $\alpha \rightarrow 0$, the gradient and Hessian of $\frac{1}{\alpha} J_{\alpha}$ is the same as J_{MS} .
- As $\alpha \rightarrow +\infty$, $A\bar{f} = 0$, then it's equivalent to minimize J_{FWI}

Outline

- 1 Overview
- 2 Matched Source Waveform Inversion

- 4 Numerical Examples**
- 5 Conclusion and Discussion

Example 1: Velocity Scan of J_{MS}

Figure: $J_{MS}[v]$ for homogeneous velocity v , $0.25 \text{ s/km} \leq v^{-1} \leq 0.75 \text{ s/km}$. Correct velocity is 2 km/s .

Example 2: Gaussian Lens

In this example, the target velocity consists of two Gaussian velocity anomalies embedded in a $v = 2\text{km/s}$ background:

$$v(x, z) = 2 - 0.6e^{-\frac{(x-0.25)^2+(z-0.3)^2}{(0.2)^2}} - 0.6e^{-\frac{(x-0.25)^2+(z-0.7)^2}{(0.1)^2}},$$

where $x \in [0, 0.5]\text{km}$, $z \in [0, 1]\text{km}$. The initial model is given by the constant velocity $v_0 = 2 \text{ km/s}$. Data is consisted of 50 shots and 99 receivers for each shot, which are uniformly distributed.

Example 2: Gaussian Lens

Example 2: Gaussian Lens

Example 2: Gaussian Lens

Figure: Extended source functions

Example 3: Big Gaussian

Figure: Low velocity Gaussian anomaly model with radius $250m \times 150m$ embedded in the constant background velocity $v_0 = 2000m/s$

Example 3: Big Gaussian

Figure: Receivers are uniformly distributed long $x_r = 1990\text{m}$ from $z_r = 10\text{m}$ to $x_r = 990\text{m}$ for each shots, shots interval is 20m . The zero-phase ricker wavelet with main frequency $f = 10\text{Hz}$ for generating the data.

Example 3: Big Gaussian

Figure: Inverted velocity after 50 iterations by MSWI (top) and FWI (bottom)

Outline

- 1 Overview
- 2 Matched Source Waveform Inversion
- 3 Analysis of Gradient and Hessian
- 4 Numerical Examples
- 5 Conclusion and Discussion**

Conclusion and Discussion

Conclusion

- Establish the relation between waveform inversion and traveltome tomography;
- Convexity of objective function is independent of frequency content.
- MSWI still get stuck in local minima due to the strong multipaths.

Discussion

- Does perfect data fitting (no cycle skipping) mean avoiding local minima;
- How do we choose the extended model space and the related annihilator.

To be cont'd

Figure: Inverted velocity after 100 iterations and 200 iterations
